governing equations

Introduction

$$K\Delta u = \Delta f \tag{1}$$

Stiffness matrix K, change in displacement Δu and change of force Δf . The change of force involves evaluation of non-linear equations that depend on displacement field.

Introduction

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

problem from the work floor: material analysis

properties of stiffness matrix K

- symmetric, positive definite: $\forall \Delta u \neq 0, \ \Delta u^T K \Delta u > 0$
- $K \in \mathbb{R}^{n \times n}$, $n >> 10^6$
- discontinuities in values matrix entries $\sim \mathcal{O}\left(10^6\right)$: ill-conditioned

Existing solvers

bottom line: no free lunch

no black box solution for large, ill-conditioned systems

- performance of PCG depends on spectrum of *K*, large jumps induce small eigenvalues, hence performance degrades when number of jumps (different materials) increases
- direct solvers (may) become expensive for large meshes
- AMG can be insensitive to jumps, however to achieve this one has to define the coarse grid specifically

Use deflation

Deflation basedoperator is not a classical pre conditioner, i.e. it is not an approximation of K. The deflation operator is a projection which, by the right choice of the projection vectors, removes eigenvalues from the spectrum of the projected system.

definition

split displacement vector u,

$$u = \left(I - P^{T}\right)u + P^{T}u, \qquad (2)$$

and let us define the projection P by,

0000000

$$P = I - KZ(Z^T KZ)^{-1} Z^T, \quad Z \in \mathbb{R}^{n \times m}$$
(3)

Iterative methods 00 0000000 Questions and references

the DPCG method

We use deflation based operator in conjunction with pre conditioning (e.g. diagonal scaling) to remove those small eigenvalues that correspond to the jumps (discontinuities) in the values of the stiffness matrix.

Deflated Pre conditioned Conjugate Gradient (DPCG) method Solve for $M^{-1}PK\Delta u = M^{-1}P\Delta f$

How to choose the deflation vectors?

- We have observed in [2]¹ that the rigid body modes of the regions corresponding to the different materials coincide with the eigenvectors of the 'jump' eigenvalues.
- By removing those rigid body modes (RBM) using deflation, we remove the corresponding 'jump' eigenvalues from the system.
- The rigid body modes of sets of finite elements can be easily computed.

Questions and references

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

How do RBM relate to stiffness matrix K?

The kernel of the element matrix of an arbitrary unconstrained finite element is spanned by the rigid body modes of the element. In 3D six rigid body modes: three translations, three rotations.

How do RBM relate to stiffness matrix K?

Theorem

We assume a splitting K = C + R such that C and R are symmetric positive semi-definite with $\mathcal{N}(C) = \text{span}\{Z\}$ the null space of C [1]². Then

$$\lambda_i(C) \le \lambda_i(PK) \le \lambda_i(C) + \lambda_{max}(PR).$$
(4)

Moreover, the effective condition number of PK is bounded by,

$$\kappa_{eff}(PK) \le \frac{\lambda_n(K)}{\lambda_{m+1}(C)}.$$
(5)

Recursive deflation

However, the definition of P given by first theorem does not provide insight in the effect of individual deflation vectors on the spectrum of PK. Introduce a recursive deflation operator which can be used for more extensive eigenvalue analysis of PK.

Definition $P^{(k)} = I - KZ_k(Z_k^{\mathrm{T}}KZ_k)^{-1}Z_k^{\mathrm{T}}$ with $Z_k = [\tilde{Z}_1, \tilde{Z}_2, ..., \tilde{Z}_k]$, where $\tilde{Z}_j \in \mathbb{R}^{n \times l_j}$ and has rank l_j .

Questions and references

Recursive deflation

Theorem Let $P^{(k)}$ and Z_k as in Definition 2, then $P^{(k)}K = P_kP_{k-1}\cdots P_1K$ where $P_{i+1} = I - \tilde{K}_i\tilde{Z}_{i+1}(\tilde{Z}_{i+1}^T\tilde{K}_i\tilde{Z}_{i+1})^{-1}\tilde{Z}_{i+1}^T$, $\tilde{K}_i = P_i\tilde{K}_{i-1}$, $\tilde{K}_1 = P_1K$, $\tilde{K}_0 = K$, $\tilde{Z}_i^T\tilde{K}_{i-1}\tilde{Z}_i^T$ and $Z_i^TKZ_i$ are non-singular because Z_i are of full rank and K is a symmetric positive definite matrix.

Recursive deflation: 1D example

Poisson equation,

$$-\frac{d}{dx}\left(c(x)\frac{du(x)}{dx}\right) = f(x), \quad x \in [0, l]$$
$$u(0) = 0, \quad \frac{du}{dx}(l) = 0$$

00000000

Recursive deflation: 1D example

Introduce a FE mesh for the line [0, I] including 3 domains $\Omega_1 = \{x_1, ..., x_4\}, \ \Omega_2 = \{x_5, ..., x_8\}$ and $\Omega_3 = \{x_9, ..., x_{13}\}.$ For sake of simplicity we will write $c_i = c(x_i)$ where i = 1, ..., 13, $x_1 = h$ and $x_{13} = I$. Furthermore because c_i is constant on each material domain we will use $c_i = c_1, \ c_i = c_2$ and $c_i = c_3$ on $\Omega_1, \ \Omega_2$ and Ω_3 respectively.

Numerical experiment: real asphalt core

Consider picture from introduction. Size of system approx. 3 million DOF, material parameters given in table below,

Table:

(a) <i>E</i> modulus materials					
aggregate	bitumen	air voids			
70000	5000	100			

Numerical experiment: real asphalt core

We compare PCG and DPCG combined with three different preconditioners,

- diagonal scaling: low cost, weak properties
- AMG smoothed aggregation, default parameters, no specific information on mesh provided: relative low set up and solve cost, designed for solving elastic equations
- AMG smoothed aggregation, approx. null space of operator and dof-to-node mapping provided: expensive set up and solve cost, high memory usage
